

Module 2 Cheatsheet: Python Data Structures Part-2

Dictionaries

Package/Method	Description	Code Example
		Example:
Creating a Dictionary	A dictionary is a built-in data type that represents a collection of key-value pairs. Dictionaries are enclosed in curly braces {}.	1. 1 2. 2
		<pre>1. dict_name = {} #Creates an empty dictionary 2. person = { "name": "John", "age": 30, "city": "New York"}</pre>
		Copied!
		Syntax:
		1. 1
Accessing Values	You can access the values in a dictionary using their corresponding keys.	<pre>1. Value = dict_name["key_name"]</pre>
		Copied!
		Example:
		1. 1 2. 2
		 name = person["name"] age = person["age"]
		Copied!
Add or modify	Inserts a new key-value pair into the dictionary. If the key already exists, the	Syntax:

about:blank 10/10/23, 3:24 PM value will be updated; otherwise, a new 1. 1 entry is created. 1. dict_name[key] = value Copied! Example: 1. 1 2. 2 1. person["Country"] = "USA" # A new entry will be created. 2. person["city"] = "Chicago" # Update the existing value for the same key Copied! Syntax: 1. 1 1. del dict_name[key] Removes the specified key-value pair from Copied! del the dictionary. Raises a KeyError if the key Example: does not exist. 1. 1 1. del person["Country"] Copied! Syntax: 1. 1 1. dict_name.update({key: value}) Copied! update() method merges the provided update() dictionary into the existing dictionary, adding or updating key-value pairs. Example: 1. 1 1. person.update({"Profession": "Doctor"})

Copied!

about:blank

10/10/23, 3.24 1 10		about.blailk
		Syntax:
	clear() method empties the dictionary, removing all key-value pairs within it. After this operation, the dictionary is still accessible and can be used further.	1. 1
clear()		<pre>1. dict_name.clear()</pre>
		Copied!
		Example:
		1. 1
		<pre>1. grades.clear()</pre>
key existence	You can check for the existence of a key in a dictionary using the in keyword	Copied!
		Example:
		1. 1 2. 2
		 if "name" in person: print("Name exists in the dictionary.")
		Copied!
		Syntax:
		1. 1
copy()	Creates a shallow copy of the dictionary. The new dictionary contains the same key- value pairs as the original, but they remain distinct objects in memory.	<pre>1. new_dict = dict_name.copy()</pre>
		Copied!
		1. 1
		2. 2
keys()	Retrieves all keys from the dictionary and converts them into a list. Useful for iterating or processing keys using list methods.	<pre>1. new_person = person.copy() 2. new_person = dict(person) # another way to create a copy of dictionary</pre>
		Copied!
		Syntax:
		1. 1
		<pre>1. keys_list = list(dict_name.keys())</pre>
alone of laterals		

about:blank

about:blank 10/10/23, 3:24 PM

Copied! Example: 1. 1 1. person_keys = list(person.keys()) Copied! Syntax: 1. 1 1. values_list = list(dict_name.values()) Extracts all values from the dictionary and Copied! values() converts them into a list. This list can be Example: used for further processing or analysis. 1. 1 1. person_values = list(person.values()) Copied! Syntax: 1. 1 1. items_list = list(dict_name.items()) Retrieves all key-value pairs as tuples and Copied! converts them into a list of tuples. Each items() tuple consists of a key and its Example: corresponding value. 1. 1 1. info = list(person.items()) Copied!

Sets

Defining Sets A set is an unordered collection of unique Example: elements. Sets are enclosed in curly braces

- 1. 1
- 2. 2

	{}. They are useful for storing distinct values and performing set operations.	<pre>1. empty_set = set() #Creating an Empty Set 2. fruits = {"apple", "banana", "orange"}</pre>
		Copied!
		Syntax:
		1. 1
		<pre>1. set_name.add(element)</pre>
add()	Elements can be added to a set using the add() method. Duplicates are automatically removed, as sets only store unique values.	Copied!
auu()		Example:
		1. 1
		 fruits.add("mango")
		Copied!
		Syntax:
		1. 1
	II d	1. set_name.remove(element)
remove()	Use the remove() method to remove a specific element from the set. Raises a KeyError if the element is not found.	Copied!
		Example:
		1. 1
		1. fruits.remove("banana")
discard()	Use the discard() method to remove a specific element from the set. ignores if not the element is not found.	Copied! Syntax:
discard()		1. 1
		<pre>1. set_name.discard(element)</pre>
		Copied!
		Example:
		1. 1

```
1. fruits.discard("apple")
                                                              Copied!
                                                             Syntax:
                                                               1. 1
                                                               1. set_name.update(iterable)
                  The update() method adds elements from
                                                              Copied!
update()
                  another iterable into the set. It maintains
                                                            Example:
                  the uniqueness of elements.
                                                               1. 1
                                                               1. fruits.update(["kiwi", "grape"])
                                                              Copied!
                                                             Syntax:
                                                               1. 1
                                                               1. set_name.clear()
                  The clear() method removes all elements
                                                              Copied!
clear()
                  from the set, resulting in an empty set. It
                  updates the set in-place.
                                                            Example:
                                                               1. 1
                                                               1. fruits.clear()
                                                              Copied!
                  The pop() method removes and returns an Syntax:
pop()
                  arbitrary element from the set. It raises a
                                                               1. 1
                  KeyError if the set is empty. Use this
                  method to remove elements when the order
                                                               1. removed_element = set_name.pop()
                  doesn't matter.
                                                              Copied!
                                                            Example:
                                                               1. 1
```

about:blank

```
1. removed_fruit = fruits.pop()
                                                            Copied!
                                                           Syntax:
                                                             1. 1
                                                             1. new_set = set_name.copy()
                                                            Copied!
                 The copy() method creates a shallow copy
copy()
                 of the set. Any modifications to the copy
                                                          Example:
                 won't affect the original set.
                                                             1. 1
                                                             1. new_fruits = fruits.copy()
                                                            Copied!
                                                           Syntax:
                                                             1. 1
                                                             2. 2
                                                             3. 3
                                                             4.4
                                                             1. union set = set1.union(set2)
                                                             2. intersection set = set1.intersection(set2)
                                                             3. difference set = set1.difference(set2)
                                                             4. sym_diff_set = set1.symmetric_difference(set2)
                 Perform various operations on sets: union,
                                                            Copied!
Set Operations
                 intersection, difference, symmetric
                                                           Example:
                  difference.
                                                             1. 1
                                                             2. 2
                                                             3. 3
                                                             4.4
                                                             1. combined = fruits.union(colors)
                                                             2. common = fruits.intersection(colors)
                                                             3. unique_to_fruits = fruits.difference(colors)
                                                             4. sym_diff = fruits.symmetric_difference(colors)
                                                            Copied!
```

The issubset() method checks if the current set is a subset of another set. It

False.

False.

returns True if all elements of the current

set are present in the other set, otherwise

Syntax:

1. 1

1. is_subset = set1.issubset(set2)

Copied!

Example:

1. 1

1. is_subset = fruits.issubset(colors)

Copied!

Syntax:

1. 1

1. is_superset = set1.issuperset(set2)

Copied!

Example:

1. 1

1. is_superset = colors.issuperset(fruits)

Copied!

issubset()

The issuperset() method checks if the current set is a superset of another set. It returns True if all elements of the other set are present in the current set, otherwise
